(Draft As accepted by PRL.)

We present results from an analysis of all data taken by the BICEP2/Keck CMB polarization experiments up to and including the 2015 observing season. This includes the first Keck Array observations at 220 GHz and additional observations at 95 & 150 GHz. The Q/U maps reach depths of 5.2, 2.9 and $26 \mu\text{K}_\text{rms}$ arcmin $^{-2}$ at 95, 150 and 220 GHz respectively over an effective area of ≈ 400 square degrees. The 220 GHz maps achieve a signal-to-noise on polarized dust emission approximately equal to that of *Planck* at 353 GHz. We take auto- and cross-spectra between these maps and publicly available WMAP and *Planck* maps at frequencies from 23 to 353 GHz. We evaluate the joint likelihood of the spectra versus a multicomponent model of lensed- $\Lambda\text{CDM}+r+\text{dust}+\text{synchrotron}+\text{noise}$. The foreground model has seven parameters, and we impose priors on some of these using external information from *Planck* and WMAP derived from larger regions of sky. The model is shown to be an adequate description of the data at the current noise levels. The likelihood analysis yields the constraint $r_{0.05} < 0.07$ at 95% confidence, which tightens to $r_{0.05} < 0.06$ in conjunction with *Planck* temperature measurements and other data. The lensing signal is detected at 8.8 σ significance. Running maximum likelihood search on simulations we obtain unbiased results and find that $\sigma(r) = 0.020$. These are the strongest constraints to date on primordial gravitational waves.

BK15 = includes all data taken up to, and including, 2015 season

Three years since BK14 – Sorry for the delay!

Experimental Strategy

- Small aperture telescopes (cheap, fast, low systematics)
- Target the 2 degree peak of the B-mode
- Integrate continuously from South Pole
- Observe 1% patch of sky
- Scan and pair difference modulation

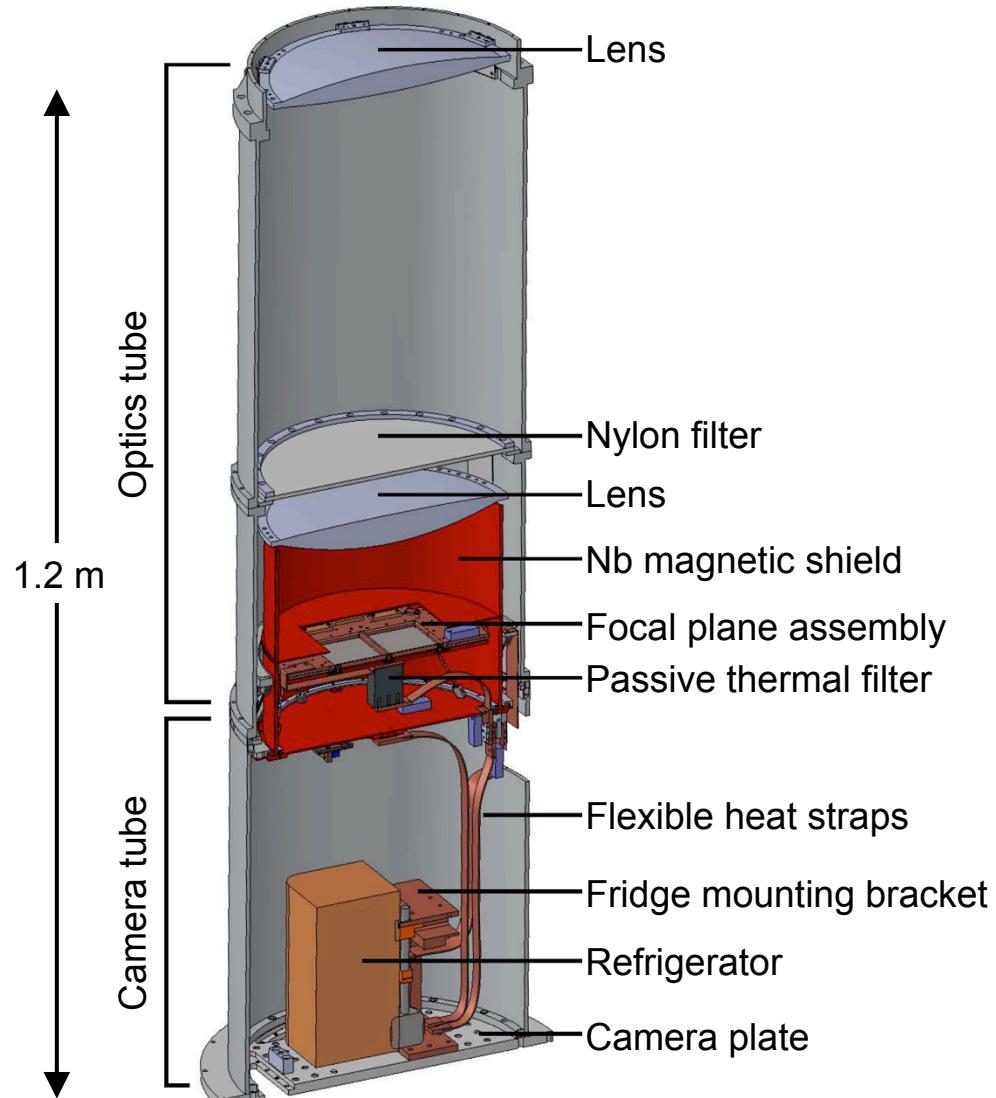

The BICEP2/Keck Telescopes

Telescope as compact as possible while still having the angular resolution to observe degree-scale features

On-axis, refractive optics allow the entire telescope to rotate around boresight for polarization modulation

Liquid helium/pulse tube cools the optical elements to 4 K

3-stage helium sorption refrigerator further cools the detectors to 0.27 K

Planar superconducting detector arrays

...designed to scale
in frequency

Up to 2013 – all 150GHz

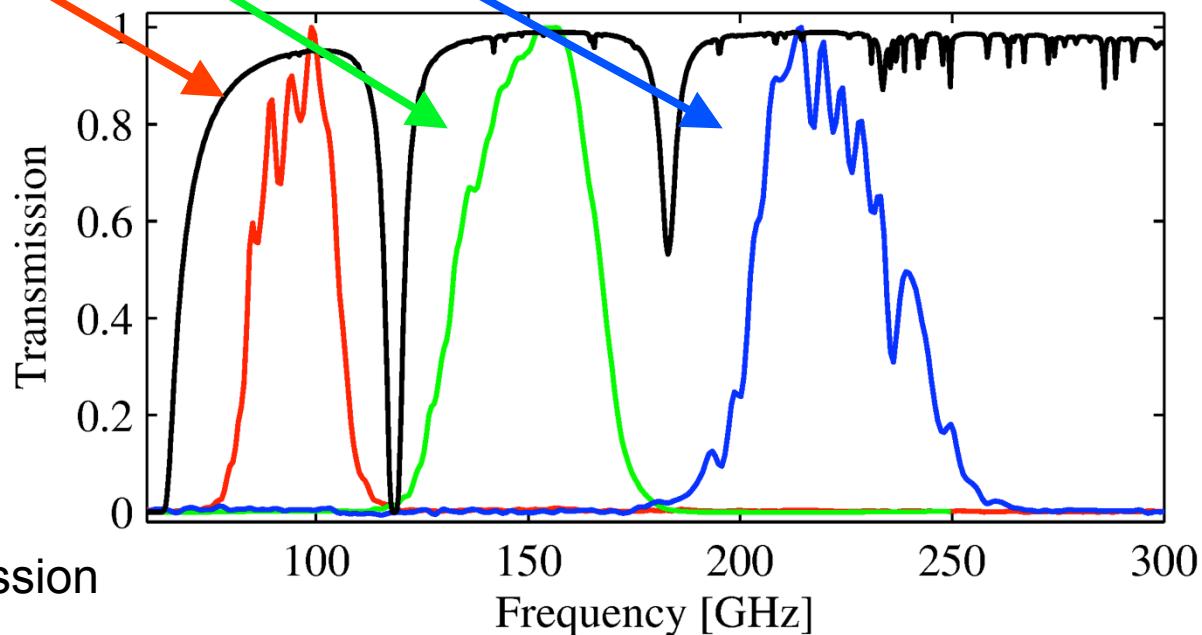

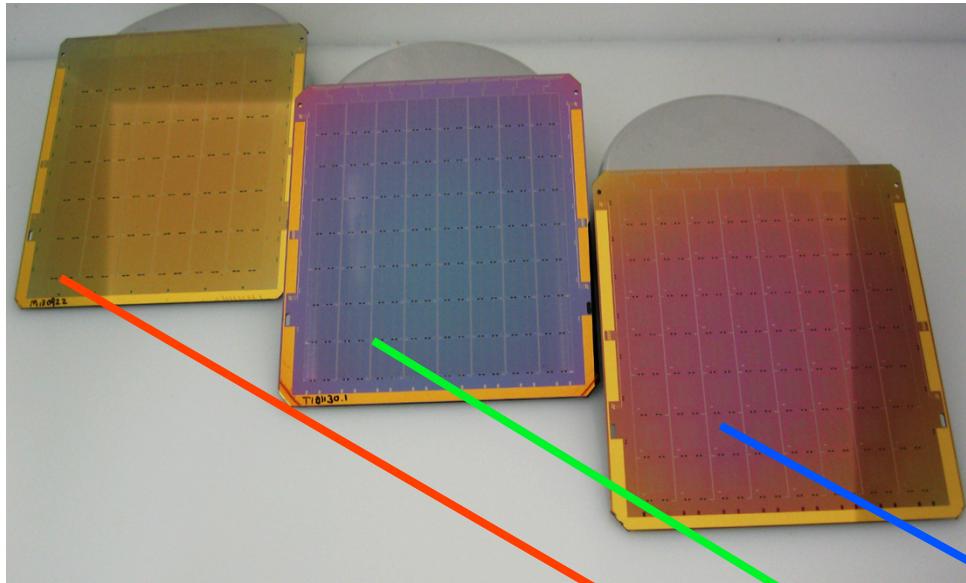

2014 – 2x95 3x150GHz

2015 – 2x95 1x150 2x220GHz

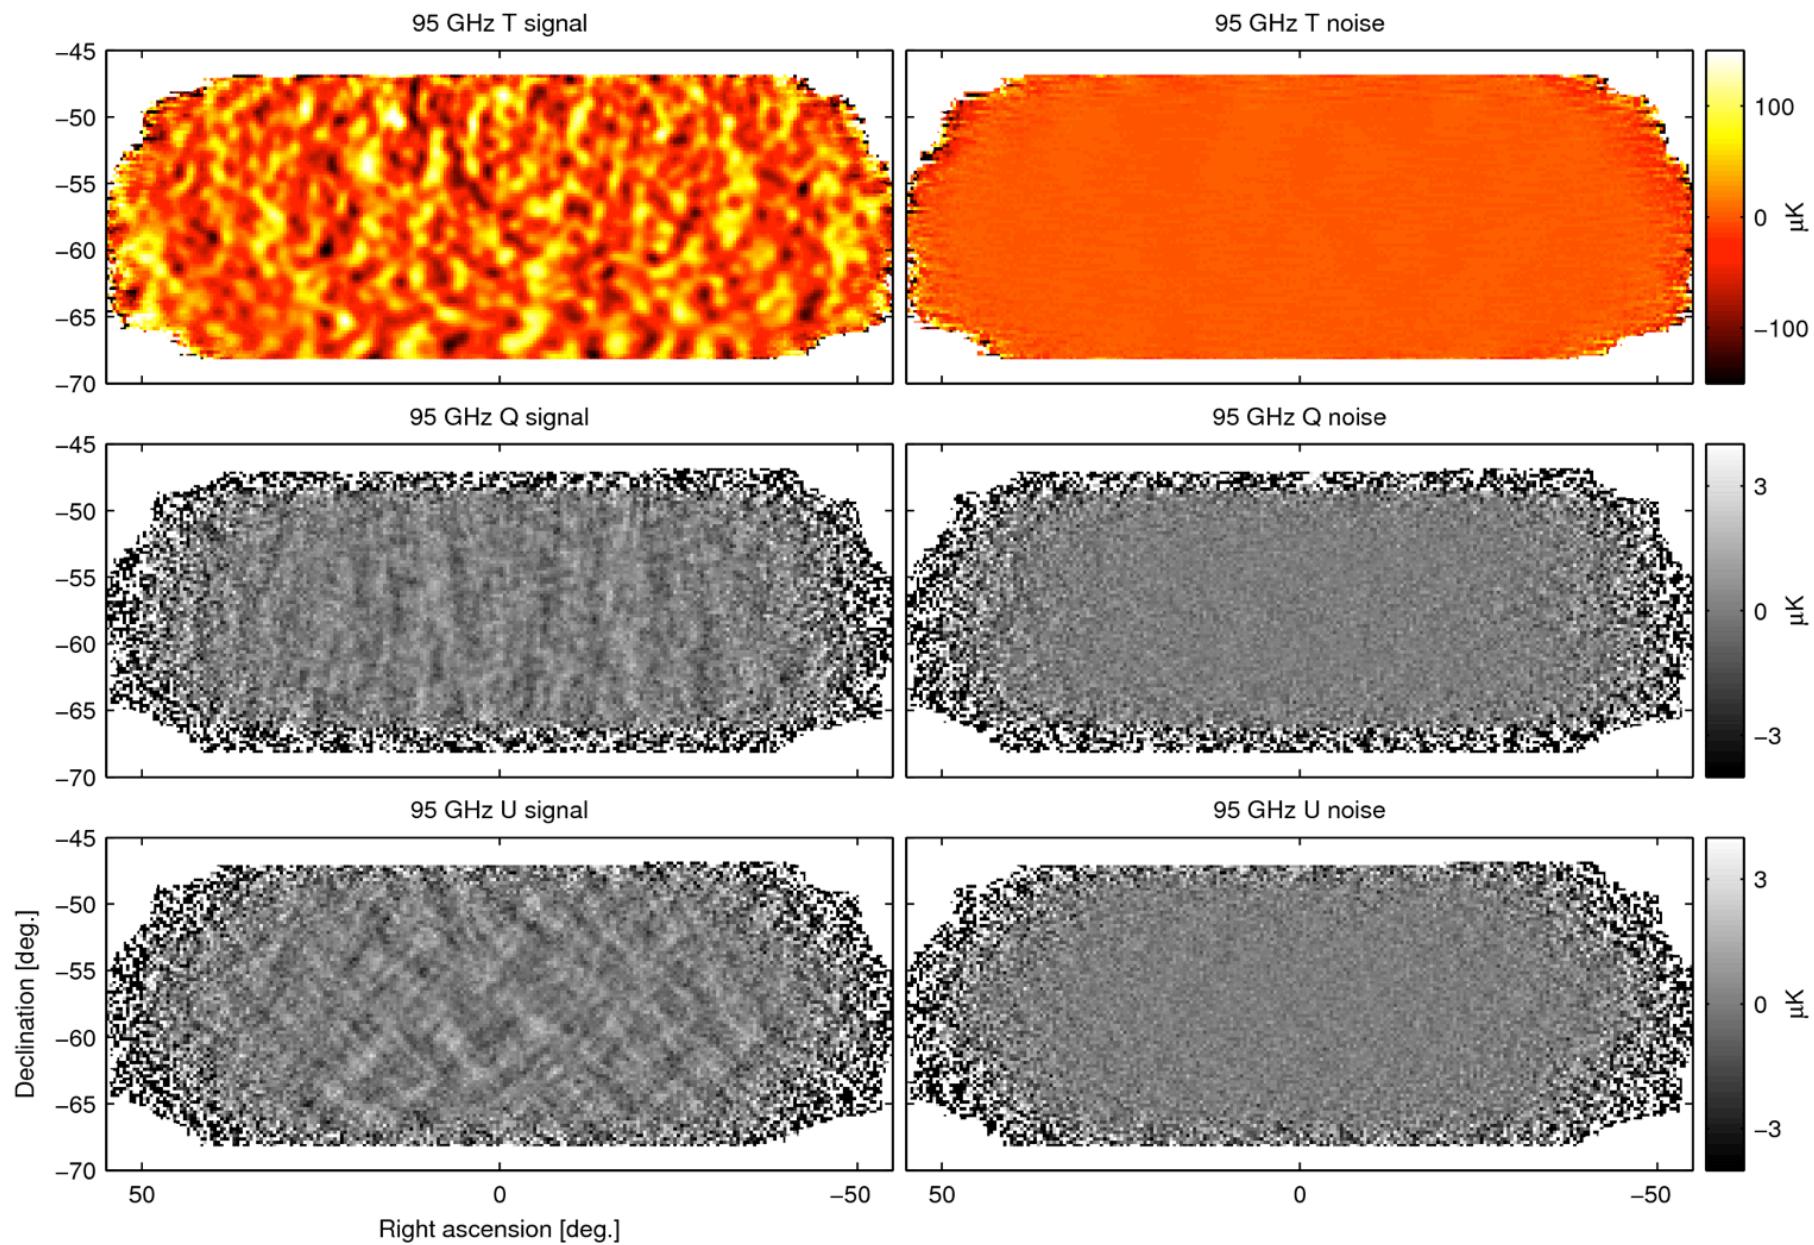

2016 – B3 1x150 4x220GHz

2017 – B3 4x220 1x270GHz

2018 – B3 4x220 1x270GHz

ABSTRACT

The characterization of the Galactic foregrounds has been shown to be the main obstacle in the challenging quest to detect primordial B -modes in the polarized microwave sky. We make use of the *Planck-HFI* 2015 data release at high frequencies to place new constraints on the properties of the polarized thermal dust emission at high Galactic latitudes. Here, we specifically study the spatial variability of the dust polarized spectral energy distribution (SED), and its potential impact on the determination of the tensor-to-scalar ratio, r . We use the correlation ratio of the C_{ℓ}^{BB} angular power spectra between the 217- and 353-GHz channels as a tracer of these potential variations, computed on different high Galactic latitude regions, ranging from 80 % to 20 % of the sky. The new insight from *Planck* data is a departure of the correlation ratio from unity that cannot be attributed to a spurious decorrelation due to the cosmic microwave background, instrumental noise, or instrumental systematics. The effect is marginally detected on each region, but the statistical combination of all the regions gives more than 99 % confidence for this variation in polarized dust properties. In addition, we show that the decorrelation increases when there is a decrease in the mean column density of the region of the sky being considered, and we propose a simple power-law empirical model for this dependence, which matches what is seen in the *Planck* data. We explore the effect that this measured decorrelation has on simulations of the BICEP2-Keck Array/*Planck* analysis and show that the 2015 constraints from those data still allow a correlation between the dust at 150 and 353 GHz of the order of the one we measure. Finally, using simplified models, we show that either spatial variation of the dust SED or of the dust polarization angle could produce decorrelations between 217- and 353-GHz data similar to those we observe in the data.

A departure of the correlation ratio from unity that cannot be attributed to a spurious decorrelation due to the cosmic microwave background, instrumental noise, or instrumental systematics... detected at more than 99% confidence

ABSTRACT

The study of polarized dust emission has become entwined with the analysis of the cosmic microwave background (CMB) polarization in the quest for the curl-like B -mode polarization from primordial gravitational waves and the low-multipole E -mode polarization associated with the reionization of the Universe. We use the new *Planck* PR3 maps to characterize Galactic dust emission at high latitudes as a foreground to the CMB polarization and use end-to-end simulations to compute uncertainties and assess the statistical significance of our measurements. We present *Planck* EE, BB, and TE power spectra of dust polarization at 353 GHz for a set of six nested high-Galactic-latitude sky regions covering from 24 to 71 % of the sky. We present power-law fits to the angular power spectra, yielding evidence for statistically significant variations of the exponents over sky regions and a difference between the values for the EE and BB spectra, which for the largest sky region are $\alpha_{EE} = -2.42 \pm 0.02$ and $\alpha_{BB} = -2.54 \pm 0.02$, respectively. The spectra show that the TE correlation and E/B power asymmetry discovered by *Planck* extend to low multipoles that were not included in earlier *Planck* polarization papers due to residual data systematics. We also report evidence for a positive TB dust signal. Combining data from *Planck* and WMAP, we determine the amplitudes and spectral energy distributions (SEDS) of polarized foregrounds, including the correlation between dust and synchrotron polarized emission, for the six sky regions as a function of multipole. This quantifies the challenge of the component-separation procedure that is required for measuring the low- ℓ reionization CMB E -mode signal and detecting the reionization and recombination peaks of primordial CMB B modes. The SED of polarized dust emission is fit well by a single-temperature modified blackbody emission law from 353 GHz to below 70 GHz. For a dust temperature of 19.6 K, the mean dust spectral index for dust polarization is $\beta_d^p = 1.53 \pm 0.02$. The difference between indices for polarization and total intensity is $\beta_d^p - \beta_d^t = 0.05 \pm 0.03$. By fitting multi-frequency cross-spectra between *Planck* data at 100, 143, 217, and 353 GHz, we examine the correlation of the dust polarization maps across frequency. We find no evidence for a loss of correlation and provide lower limits to the correlation ratio that are tighter than values we derive from the correlation of the 217- and 353-GHz maps alone. If the *Planck* limit on decorrelation for the largest sky region applies to the smaller sky regions observed by sub-orbital experiments, then frequency decorrelation of dust polarization might not be a problem for CMB experiments aiming at a primordial B -mode detection limit on the tensor-to-scalar ratio $r \sim 0.01$ at the recombination peak. However, the *Planck* sensitivity precludes identifying how difficult the component-separation problem will be for more ambitious experiments targeting lower limits on r .

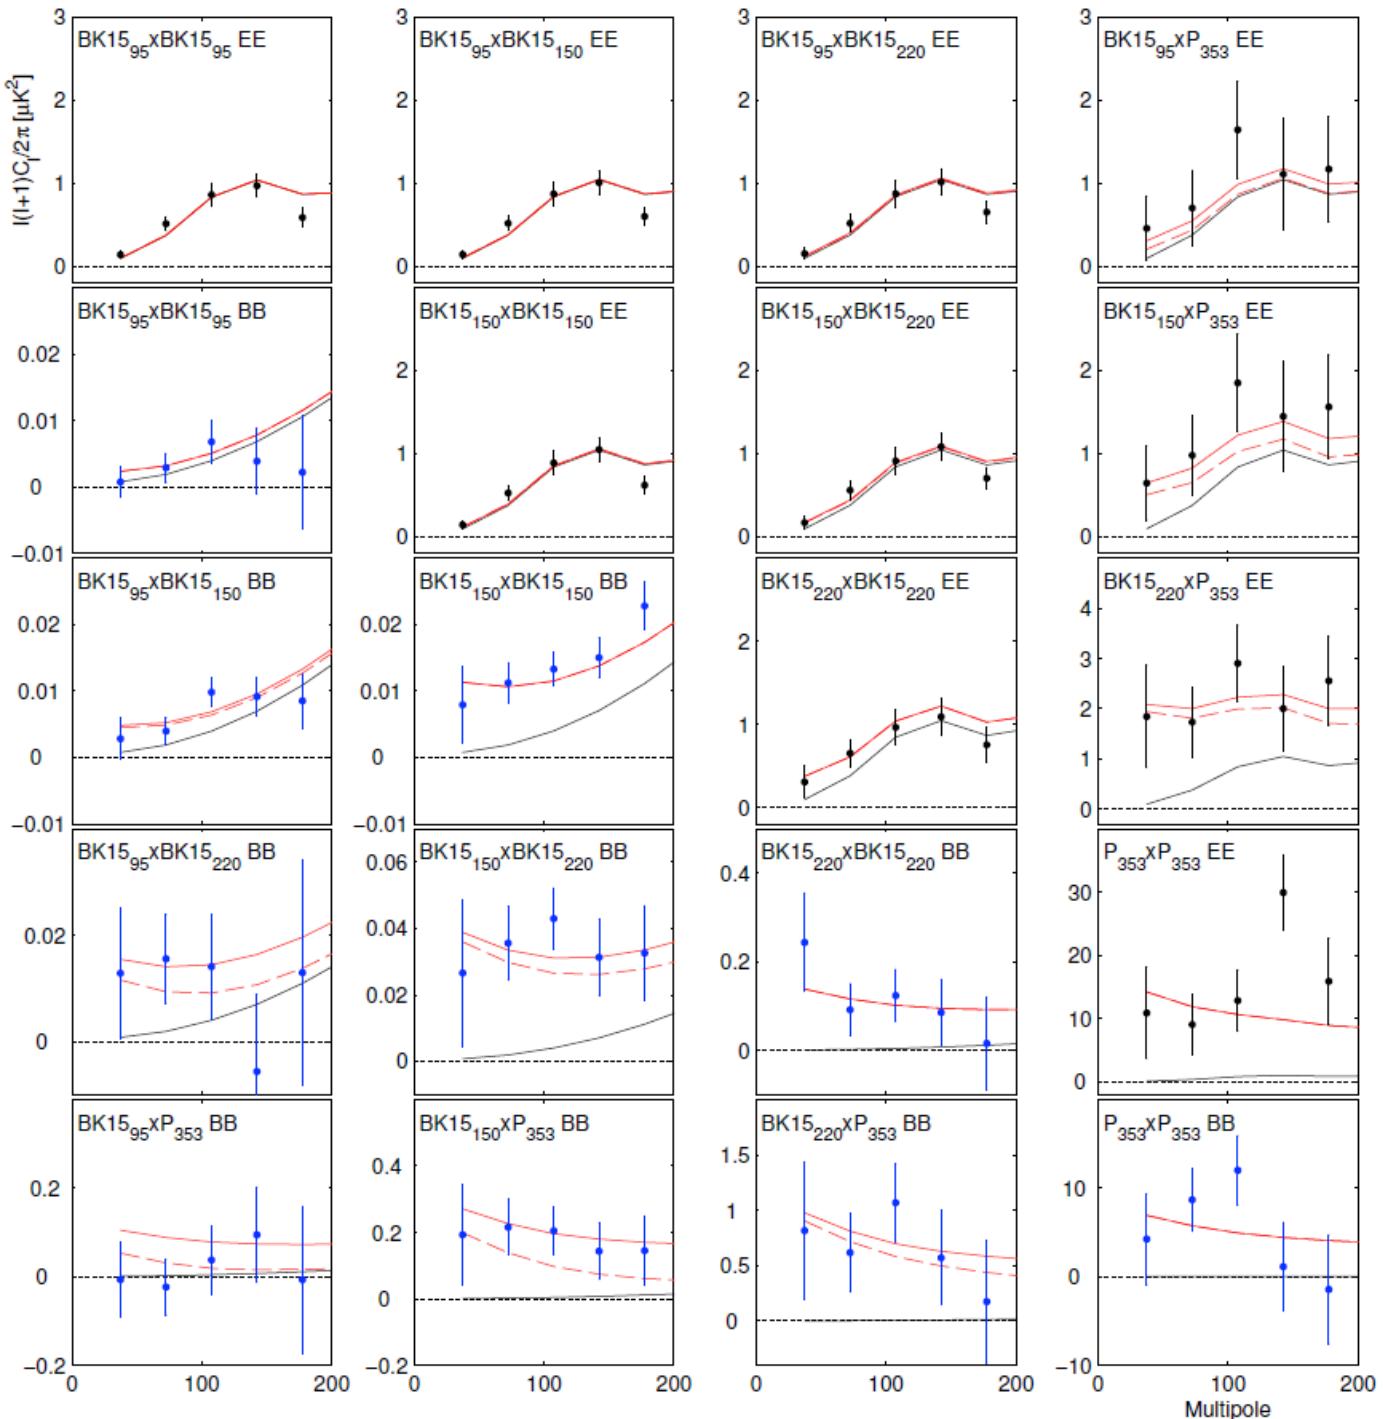

We find no evidence for a loss of correlation.

Include dust correlation parameter?

- The standard BK15 marginalized likelihood analysis (COSMOMC style) is unbiased for r – i.e. when run on lensed-LCDM+dust+noise sims 50% of the r curves peak at zero.
- However, if add a dust correlation parameter and restrict to physical range (<1) then r becomes biased – i.e. 72% of curves peak at zero
- This is because r and dust correlation parameter are partially degenerate
- Can run alternate maximum likelihood searches where parameters are allowed to take unphysical values ($r < 0$ and dust correlation > 1)
- These really should be unbiased...

BK15 ML Search Results for Sims

Conclusions

- BICEP/Keck lead the field in the quest to detect or set limits on inflationary gravitational waves:
- New BK15 result sets $r_{0.05} < 0.07$ and $\sigma(r) = 0.020$
- BICEP3 is running since 2016 with high sensitivity at 95GHz, and Keck Array continues to run at 220GHz, plus new 270GHz band
- We intend to go straight to BK17 (or BK18) analysis which will approach $\sigma(r) = 0.010$
- BICEP Array is under construction and will go much further
- Next gen. receivers in five bands
- Delensing in conjunction with SPT3G is under development
- Project BK23 $\sigma(r) < 0.003$
- And beyond that is mega experiment CMB-S4...
- Foreground complexity will remain a serious issue – the hope is that we can measure it *and* constrain r simultaneously without a large loss of sensitivity. Additional ground/balloon measurements at low/high frequencies may be able to help.
